The author’s research was sponsored by NSERC Grant A3456 and FQRNT Grant 90-ER-0291.
Abstract. We consider random patricia trees constructed from $n$ i.i.d. sequences of independent equiprobable bits. We study the height $H_n$ (the maximal distance between the root and a leaf), and the minimal fill-up level $F_n$ (the minimum distance between the root and a leaf). We give probabilistic proofs of

$$
\frac{H_n - \log_2 n}{\sqrt{2 \log_2 n}} \to 1 \text{ almost surely}
$$

and

$$
\frac{F_n - \log_2 n}{\log_2 \log n} \to -1 \text{ almost surely.}
$$

Keywords and phrases. Trie, patricia tree, probabilistic analysis, strong convergence, height of a tree.

Introduction.

**Tries** are efficient data structures that were initially developed and analyzed by Fredkin (1960) and Knuth (1973). The tries considered here are constructed from \( n \) independent infinite binary strings \( X_1, \ldots, X_n \). Each string defines an infinite path in a binary tree: a 0 forces a move to the left, and a 1 forces a move to the right. For storage purposes, \( n \) nodes are identified, one per path, which will represent the \( n \) infinite strings; we say that \( X_i \) is stored at node \( i \). The tree is now pruned so that it has just \( n \) leaves at the \( n \) representative nodes. Observe that no representative node is allowed to be an ancestor of any other representative node. The trie is the minimal tree of the type defined above. This implies that every internal (non-leaf) node has at least two leaves in its collection of descendants.

In the **uniform trie model**, the bits in the string \( X_1 \) are i.i.d. Bernoulli random variables with success probability \( p = 0.5 \). For other models, we refer to Devroye (1982, 1984), Régnier (1988), Szpankowski (1988) and Pittel (1985).

The number of steps required to locate a leaf is equal to the length of the path linking \( X_i \) and the root. We call this distance the **depth** \( D_{ni} \) of node \( i \) in a trie of size \( n \). When we want to give guarantees to a potential user about the time required for a look-up, then we should really refer to the **height** \( H_n \coloneqq \max_i D_{ni} \). Another quantity of interest to the user is the lower bound on time required to access an element in the structure, i.e. \( F_n \coloneqq \min_i D_{ni} \).

The asymptotic behavior of tries under the uniform trie model is well-known. The height is studied by Régnier (1981), Mendelson (1982), Flajolet and Stéyaert (1982), Flajolet (1983), Devroye (1984), Pittel (1985, 1986), and Szpankowski (1988, 1989). For the depth of a node, see e.g. Pittel (1986), Jacquet and Régnier (1986), Flajolet and Sedgewick (1986), Kirschenhofer and Prodinger (1986), and Szpankowski (1988). For example, it is known that

\[
H_n / \log_2 n \to 2 \quad \text{almost surely}.
\]

The limit law of \( H_n \) was obtained in Devroye (1984), and laws of the iterated logarithm for the difference \( H_n - 2 \log_2 n \) can be found in Devroye (1990).

**Patricia** is a space efficient improvement of the classical trie discovered by Morrison (1968) and first studied by Knuth (1973). It is simply obtained by removing from the trie all internal nodes with one child. Thus, it necessarily has \( n \) leaves and \( n - 1 \) internal nodes. The trie from which it is deduced is called the associated trie. All parameters of Patricia such as \( H_n \) and \( F_n \) improve over those of the associated trie: Pittel (1985) has shown that \( H_n / \log_2 n \to 1 \) almost surely, which constitutes a 50% improvement over the trie. For other properties, see Knuth (1973), Flajolet and Sedgewick (1986), Kirschenhofer and Prodinger (1986), Szpankowski (1988), and Kirschenhofer, Prodinger and Szpankowski (1989). Recently, Pittel and Rubin (1990) and Pittel (1991) showed that

\[
\frac{H_n - \log_2 n}{\sqrt{2 \log_2 n}} \to 1 \quad \text{almost surely}.
\]

This result was obtained by a profound combinatorial analysis based on generating functions. Aldous and Shields (1988) showed that the same property holds true for the digital search tree, another modification of the trie with properties typically similar to those of Patricia trees. Interestingly, their proof was purely probability theoretical. This led us to believe that the asymptotic behavior of \( H_n \) and \( F_n \) should be obtainable for Patricia trees by purely probabilistic methods as well. The main results can be formulated as follows.
Theorem 1. In a sequence of Patricia trees constructed from an i.i.d. sequence \( X_1, X_2, \ldots \), we have

\[
\frac{H_n - \log_2 n}{\sqrt{2 \log_2 n}} \to 1 \quad \text{almost surely.}
\]

Theorem 2. In a sequence of Patricia trees constructed from an i.i.d. sequence \( X_1, X_2, \ldots \), we have

\[
\frac{F_n - \log_2 n}{\log_2 \log n} \to -1 \quad \text{almost surely.}
\]

The point of this paper is that both results can be obtained by standard probabilistic methods, such as Poissonization, exponential inequalities, and various embeddings.

Trees and cell occupancies.

It helps to think in terms of an infinite binary tree in which each \( X_i \) carves out an infinite path, left edges corresponding to zeros, and right edges to ones. The length of the longest common prefix of two infinite strings \( x \) and \( y \) is denoted by \( \ell(x, y) \). The collection of all infinite paths \( y \) for which \( \ell(x, y) = k \) is denoted by \( L(x, k) \). It is clear that for a given \( x \), the sets \( L(x, k), k \geq 0 \), are disjoint. The point of this is that the depth of \( X_1 \) in the Patricia tree can be characterized in terms of the occupancies of the sets \( L(X_1, k) \). For later reference, \( |L(x, k)| \) is the number of \( X_j \)'s, \( 1 \leq j \leq n \), that belong to \( L(x, k) \). Thus, \( \sum_k |L(x, k)| \leq n \), with equality occurring if and only if \( x \) is not one of the \( X_i \)'s. Also, \( O(x, k) \) def = \( I_{|L(x, k)| > 0} \). Note, in particular, that \(|.\)| is not the ordinary cardinality operator.

All \( D_n \)'s are identically distributed. From elementary considerations, we have

\[
D_{n1} = \sum_{k=0}^{\infty} I_{O(X_1, k)} . \tag{1}
\]

Without work, we conclude

\[
\mathbb{E}D_{n1} = \sum_{k=0}^{\infty} \mathbb{P}\{|L(X_1, k)| > 0\}
\]

\[
= \sum_{k=0}^{\infty} \left( 1 - \mathbb{P}^{n-1}\{X_2 \notin L(X_1, k)|X_1\} \right)
\]

\[
= \sum_{k=0}^{\infty} \left( 1 - (1 - 1/2^{k+1})^{n-1} \right)
\]

because for any \( x \), \( \mathbb{P}\{X_1 \in L(x, k)\} = 1/2^{k+1} \). This suffices to establish that \( \mathbb{E}D_{n1} = \log_2 n + O(1) \). It is equally easy to prove that \( \mathbb{V}D_{n1} = O(1) \).

For the study of \( H_n \), we need rather exact information regarding the upper tail of the distribution of \( D_{n1} \). The following basic inequality is helpful in this respect.

Proposition 1. For \( a \geq 1 \) and \( n \geq 2 \), we have

\[
\mathbb{P}\{D_{n1} \geq \log_2 n + \sqrt{a \log_2 n}\} \leq e^{a/2}(n - 1)^{-a/2} .
\]
**Proof.** Take \( t = \log_2(n - 1) + \sqrt{a \log_2(n - 1)} \). From (1) and Chernoff’s bounding method (Chernoff, 1952) we see that for \( \lambda > 0 \),

\[
P(D_{n1} \geq t|X_1) \leq e^{-\lambda t} \mathbb{E}\{ \prod_{k=0}^{\infty} e^{\lambda O(X_{1,k})} |X_1} \}
\]

\[
\leq e^{-\lambda t} \prod_{k=0}^{\infty} \mathbb{E}\{ e^{\lambda O(X_{1,k})} |X_1} \}
\]

by a property of the multinomial distribution. Indeed, given \( X_1, |L(X_1, 0)|, |L(X_1, 1)|, \ldots \) is multinomially distributed. It is known (see e.g. Esary, Proschan and Walkup, 1967, or Joag-Dev and Proschan, 1983) that for a multinomial random vector \( Y_1, Y_2, \ldots \),

\[
\mathbb{E}\prod_i f_i(Y_i) \leq \prod_i \mathbb{E} f_i(Y_i),
\]

where the \( f_i \)’s are increasing positive functions. Taking the expectation with respect to \( X_1 \) yields the following bound:

\[
P(D_{n1} \geq t) \leq e^{-\lambda t} \prod_{k=0}^{\infty} (1 + (e^\lambda - 1)(1 - (1 - 2^{-2k+1})^{n-1})))
\]

\[
\leq e^{-\lambda t} \prod_{k=0}^{\infty} \left( 1 + (e^\lambda - 1) \min \left( 1, \frac{n-1}{2k+1} \right) \right). \tag{2}
\]

The product will be split into three parts,

\[
\prod_{k=0}^{j-1} \times \prod_{k=j}^{m-1} \times \prod_{k=m}^{\infty},
\]

where we define

\[
\begin{align*}
  j &= \left\lfloor \log_2(n - 1) \right\rfloor \\
  m &= \left\lfloor (\lambda + \log(n-1)) / \log 2 \right\rfloor \\
  \lambda &= t \log 2 - \log(n - 1).
\end{align*}
\]

Note that for \( a \geq 1 \) and \( n \geq 2 \), we have \( 0 \leq j \leq m \). We obtain the following:

\[
\prod_{k=0}^{j-1} (1 + (e^\lambda - 1)) \leq e^{\lambda j},
\]

\[
\prod_{k=j}^{m-1} \left( 1 + (e^\lambda - 1) \frac{n-1}{2k+1} \right) \leq \prod_{k=j}^{m-1} e^{\lambda \frac{n-1}{2k+1}} \left( 1 + 2^{-2k+1}/((n-1)e^\lambda) \right)
\]

\[
\leq \left( (n-1)e^\lambda \right)^{m-j} 2^{-m(m+1)/2+j(j+1)/2} \exp \left( \sum_{k=j}^{m-1} 2^{k+1}/((n-1)e^\lambda) \right)
\]

\[
\leq 2^{(m-j)-m^2/2+j^2/2-(m-j)/2} \exp \left( 2^{m+1}/((n-1)e^\lambda) \right)
\]

\[
\leq 2^{(m-j)-m^2/2+j^2/2-(m-j)/2} e^{2},
\]

5
\[
\prod_{k=m}^{\infty} \left(1 + (e^\lambda - 1) \frac{n-1}{2^{k+1}}\right) \leq \prod_{k=m}^{\infty} \left(1 + e^\lambda \frac{n-1}{2^{k+1}}\right) \\
\leq \exp \left(\sum_{k=m}^{\infty} (n-1) \frac{e^\lambda}{2^{k+1}}\right) \\
= \exp \left((n-1) \frac{e^\lambda}{2^m}\right) \\
\leq e^2.
\]

Combining all this shows that
\[
P\{D_{n_1} \geq t\} \leq \exp \left(4 + \lambda(j-t) \right) \frac{2^l(m-j)-m^2/2+j^2/2-(m-j)/2}{(m-t)-m^2/2+j^2/2} \\
\leq \exp \left(4 + (j-t) \log(n-1) \right) \frac{2^l(m-t)-m^2/2+j^2/2}{(m-t)-m^2/2+j^2/2} \\
\leq e^{4/2} \left(1/2 \log_2(n-1)+1/2+t \log_2(n-1)-t^2/2\right) \\
= e^{9/2} \left(1/2 - (a/2) \log_2(n-1)\right),
\]

which was to be shown. □

The fill-up level of Patricia trees.

**Proposition 2.** For all \(a > 1\),
\[
P\{F_n < \log_2 n - a \log_2 \log n \ i.o. \} = 0.
\]

**Proof.** Define \(k = \lfloor \log_2 n - a \log_2 \log n \rfloor\). If \(\min_i D_{ni} < k\), then one of the \(2^k\) possible prefix strings of length \(k\) does not occur among \(X_1, \ldots, X_n\). Thus, by symmetry,
\[
P\{\min_{1 \leq i \leq n} D_{ni} < k\} \leq 2^k P\{\text{no } X_i \text{ starts with } k \text{ zeroes}\}
\]
\[
= 2^k (1 - 1/2^k)^n \\
\leq 2^k e^{-n/2^k} \\
\leq \exp \left(\log n - (\log n)^a - a \log \log n\right) \\
\rightarrow 0.
\]

The upper bound is also summable in \(n\) for all \(a > 1\), so Proposition 2 follows by the Borel-Cantelli lemma. □

Hoeffding (1963) has developed useful exponential inequalities for tail probabilities of sums of independent random variables. The generalization of these inequalities to martingales (Hoeffding, 1963, Azuma, 1967) has led to interesting applications in combinatorics and the theory of random graphs (for a survey, see McDiarmid, 1989). The following extension of Hoeffding’s inequality is useful for random
variables that are complicated functions of independent random variables, and that are relatively robust
to individual changes in the values of the random variables.

**Lemma 1.** (McDiarmid, 1989) Let $X_1, \ldots, X_n$ be independent random variables taking values in a set $A$, and assume that $f : A^n \to \mathbb{R}$ satisfies

$$
\sup_{x_1, \ldots, x_n, x'_1, \ldots, x'_n \in A} |f(x_1, \ldots, x_n) - f(x_1, \ldots, x'_1, x_i, x_{i+1}, \ldots, x_n)| \leq c_i, \ 1 \leq i \leq n.
$$

Then

$$
P\{|f(X_1, \ldots, X_n) - \mathbb{E}f(X_1, \ldots, X_n)| \geq t\} \leq 2e^{-2t^2/\sum_{i=1}^n c_i^2}.
$$

**Proposition 3.** For all $a < 1$,

$$
P\{F_n > \log_2 n - a \log_2 \log n \text{ i.o.} \} = 0.
$$

**Proof.** Define $k = [\log_2 n - a \log_2 \log n]$. We note that $D_{ni}$ is smaller than the corresponding value in the associated trie. Thus, we need only prove Proposition 3 for the ordinary trie. For the remainder of this proof, $D_{ni}$ thus denotes a depth in the associated trie. Fix an integer $m < n$, and for $1 \leq i \leq m$ define $D^*_ni$ as the depth of node $X_i$ in the trie formed by $X_i$ and $X_{m+1}, \ldots, X_n$. If $l(X_i, X_j) \leq k$ for all $1 \leq j \leq m$, then $D_{ni} > k$ if and only if $D^*_ni > k$. Let $J$ be the collection of all indices $i \leq m$ such that its prefix of length $k$ has not occurred among $X_1, \ldots, X_{i-1}$. Observe that

$$
P\{\min_{1 \leq i \leq n} D_{ni} > k\} \leq P\{\min_{1 \leq i \leq n} D^*_ni > k\}
$$

$$
\leq P\{\min_{1 \leq i \leq m} D^*_ni > k\}
$$

$$
\leq P\{\min_{i \in J} D^*_ni > k\}.
$$

We condition on $X_1, \ldots, X_m$, and let $|J|$ be the cardinality of $J$. Let $A_i$ be the event

$$
\max_{m+1 \leq j \leq n} l(X_i, X_j) \geq k.
$$

Using the association inequality for the multinomial distribution used earlier, we have

$$
P\{\min_{i \in J} D^*_ni > k|X_1, \ldots, X_m\} \leq P\{\cap_{i \in J} A_i|X_1, \ldots, X_m\}
$$

$$
\leq \prod_{i \in J} P\{A_i|X_i\}
$$

$$
= \prod_{i \in J} \left(1 - P^{n-m}\{l(X_1, X_2) < k\}\right)
$$

$$
= \prod_{i \in J} \left(1 - (1 - 1/2^k)^{n-m}\right)
$$

$$
\leq \exp\left(-|J|(1 - 1/2^k)^{n-m}\right).
$$
Collecting all this shows that
\[ P\{F_n > k\} \leq E\left\{ \exp(-|J|(1 - 1/2^k)^{m-n}) \right\}. \]

Note that $|J|$ is a function governed by Lemma 1, provided that we replace $n$ by $m$ and $c_i$ by 1. We have
\[ P\{|J| - E|J| > t\} \leq 2 \exp(-2t^2/m), \]
and, in particular,
\[ P\{|J| < E|J|/2\} \leq 2 \exp(-E^2|J|/2m). \]

Observe that
\[ E|J| = 2^{k}\left(1 - (1 - 1/2^k)^m\right) \geq 2^k\left(1 - (1 - m/2^k + m^2/2^{2k+1})\right) = m\left(1 - m/2^{k+1}\right). \]
Thus,
\[ P\{F_n > k\} \leq 2 \exp(-E^2|J|/2m) + \exp(-(1/2)E|J|(1 - 1/2^k)^{m-n}). \quad (3) \]

We take $m = [n/log n]$. Since $2^k \geq n/(log n)^a$, we note that $m/2^k \to 0$. The exponent in the first term of (3) is
\[ -E^2|J|/2m \sim -m/2. \]

The exponent in the second term of (3) is
\[ -(1/2)E|J|(1 - 1/2^k)^{m-n} \leq -m(1/2 + o(1))e^{-(m-n)/(2^k-1)} \sim -(m/2)e^{-n/2^k} \leq -(1/2) \exp(log m - (log n)^a) = -m^{1+o(1)}. \]
We have
\[ P\{F_n > k\} \leq \exp(-(n/log n)^{1+o(1)}). \]

The upper bound is summable in $n$, so that Proposition 3 follows by the Borel-Cantelli lemma.

Propositions 2 and 3 together imply
\[ \frac{F_n - log_2 n}{log_2 log n} \to -1 \quad \text{almost surely.} \]

**The height of Patricia trees.**

In the associated trie, it is very likely that there exists a leaf at distance at least $k = \lfloor log_2 n + (2 - \epsilon)log_2 n \rfloor$ from the root with the property that the first $k$ nodes on its path from the root all have two children, and are thus not deleted when the Patricia tree is constructed. This argument leads to a lower bound for $H_n$ (proposition 5 below). An upper bound can be obtained trivially from the large deviation result for $D_{n1}$ given in proposition 1. See proposition 4 below.
Proposition 4. For all $a > 2$, 

$$
\mathbb{P}\{H_n \geq \log_2 n + \sqrt{a \log_2 n \text{ i.o.}} \} = 0 .
$$

Proof. Define $t(n) = \log_2 n + \sqrt{a \log_2 n}$. From Proposition 1,

$$
\mathbb{P}\{H_n \geq t(n)\} \leq n \mathbb{P}\{D_{n1} \geq t(n)\} \leq e^{9/2} n (n-1)^{-a/2} = O(n^{(2-a)/2}) .
$$

(4)

Next, with $n_i = 2^i$, the monotonicity of $H_n$ and of $t(n)$ imply that we need only show that $H_{n_i+1} > t(n_i)$ finitely often almost surely. For $i$ large enough, we have $t(n_i+1) < t(n_i) + 2$. Thus, the Proposition follows by the Borel-Cantelli lemma if for all $a > 0$, 

$$
\sum_{i=1}^{\infty} \mathbb{P}\{H_{n_i} \geq t(n_i)\} < \infty .
$$

This is immediate from (4). $\blacksquare$

Proposition 5. For all $a < 2$, 

$$
\mathbb{P}\{H_n \leq \log_2 n + \sqrt{a \log_2 n \text{ i.o.}} \} = 0 .
$$

Proof. Assume without loss of generality that $a > 4/3$. Define the following quantities:

$$
k = \lfloor \log_2 n - 2 \log_2 \log n \rfloor ;
$$

$$
m = \lceil n^{a-1} \rceil ;
$$

$$
l = \lfloor \sqrt{(3a-4) \log_2 n} \rfloor .
$$

The integer $m$ is used to split the data into two parts. We will show that 

$$
\sum_{n=1}^{\infty} \mathbb{P}\{H_n \leq k + l\} < \infty .
$$

The proposition then follows by the Borel-Cantelli lemma. Indeed, for fixed $\epsilon > 0$, by choosing $a$ close enough to 2, we can make $k + l$ bigger than $\log_2 n + \sqrt{(2-\epsilon) \log_2 n}$. The proof is greatly simplified if we use an embedding argument. Let $X_1, X_2, \ldots$ be an i.i.d. sequence of infinite strings, defining an infinite sequence of patricia trees and associated tries. It is easy to see that $D_{ni}$ is an increasing function of $n$ for fixed $i$. Thus, $H_n$ is also increasing in $n$. Hence, if we let $N$ be a Poisson $((n-m)/2)$ random variable independent of the sequence of $X_i$’s, we note that 

$$
\mathbb{P}\{H_n \leq k + l\} \leq \mathbb{P}\{H_{m+N} \leq k + l, n \leq n - m\} + \mathbb{P}\{N > n - m\}
\leq \mathbb{P}\{H_{m+N} \leq k + l\} + \mathbb{P}\{N > n - m\}
\leq \mathbb{P}\{H_{m+N} \leq k + l\} + (\sqrt{\epsilon}/2)^{n-m} .
$$

The inequality for the Poisson tail follows from Chernoff’s bound: for $t > 0$, 

$$
\mathbb{P}\{N > n - m\} \leq e^{t(N - n + m)} = e^{((n-m)/2)(e^t-1) - t(n-m)} = (\sqrt{\epsilon}/2)^{n-m} ,
$$

9
where we took \( t = \log 2 \). Clearly, we need only show that
\[
\sum_{n=1}^{\infty} P\{H_{m+N} \leq k + l\} < \infty .
\]

Let \( J \) be the subset of \( \{1, \ldots, m\} \) such that \( i \in J \) if and only if \( l(X_i, X_j) < k \) for all \( j < i \). Thus, \( \{X_i, i \in J\} \) is a collection of strings with different prefixes of length \( k \). Let us define the event \( G \) (for "good") by
\[
G \overset{\text{def}}{=} \{ |J| \geq \mathbb{E}|J|/2 \} .
\]

From the proof of Proposition 3, we see that \( \mathbb{E}|J| \geq m(1 - m/2^{k+1}) \sim m \), and that
\[
P\{G^c\} \leq 2 \exp(-\mathbb{E}^2|J|/2m) \leq 2 \exp(-(1/2 + o(1))m) ,
\]
which is summable in \( n \). This reduces our problem to that of proving
\[
\sum_{n=1}^{\infty} P\{H_{m+N} \leq k + l, G\} < \infty . \tag{5}
\]

Let us call \( L(x, d) \) the set of all strings \( y \) with \( l(x, y) = d \), and let \( |L(x, d)| \) denote the cardinality of that set, when intersected with \( \{X_{m+1}, \ldots, X_{m+N}\} \). We have the following inclusion of events:
\[
[H_{m+N} \leq k + l] \cap G
\subseteq G \cap \left\{ \cap_{i \in J} \bigcup_{d=0}^{k+l} [||L(X_i, d)| = 0]\right\}
\subseteq \left\{ \bigcup_{i=1}^{m} \bigcup_{d=0}^{k} [||L(X_i, d)| = 0]\right\} \cup \left\{ G \cap \left\{ \cap_{i \in J} \bigcup_{d=k+1}^{k+l} [||L(X_i, d)| = 0]\right\}\right\} .
\]

The two events on the right-hand side are dealt with separately. First of all,
\[
P\left\{ \bigcup_{i=1}^{m} \bigcup_{d=0}^{k} [||L(X_i, d)| = 0]\right\} \leq m(k + 1)P\{||L(X_1, k)| = 0\}
= m(k + 1) \exp\left(-\frac{n-m}{2}2^{-(k+1)}\right)
\leq n(\log_2 n + 1) \exp\left(-(1 - m/n)(\log n)^2\right) ,
\]
which is summable in \( n \), as required. We can use the fundamental property of the Poisson distribution,
and the fact that the sets $L(X_i, d)$ for $d \geq k + 1$ and $i \in J$ are disjoint. This yields

$$\begin{align*}
P \left\{ G \cap \left\{ \cap_{i \in J} \bigcup_{d=k+1}^{k+l} \{ |L(X_i, d)| = 0 \} \right\} \mid X_1, \ldots, X_m \right\} \\
= IG \prod_{i \in J} P \left\{ \cap_{d=k+1}^{k+l} \{ |L(X_i, d)| = 0 \} \mid X_i \right\} \\
= IG \prod_{i \in J} \left( 1 - P \left\{ \cap_{d=k+1}^{k+l} \{ |L(X_i, d)| > 0 \} \mid X_i \right\} \right) \\
\leq IG \exp \left( - \sum_{i \in J} \prod_{d=k+1}^{k+l} P \{ |L(X_i, d)| > 0 \mid X_i \} \right) \\
= IG \exp \left( - |J| \prod_{d=k+1}^{k+l} \left( 1 - \exp \left( - \frac{n-m}{2} \right) \right) \right) \\
\leq \exp \left( - (|J|/2) \prod_{d=k+1}^{k+l} (1 - \exp (-(n-m)/2d)) \right).
\end{align*}$$

Because the upper bound does not depend upon $X_1, \ldots, X_m$, it remains valid if we take expectations to rid ourselves of the conditioning. Property (5) follows if we can show that this upper bound is summable in $n$. Call $M$ minus the logarithm of the upper bound. Using $1 - e^{-u} \geq \min(1, u)/2$, valid for $u > 0$, we have

$$M \geq m 2^{-l} \left( \frac{1}{2} + o(1) \right) \prod_{d=k+1}^{k+l} \min(1, (n-m)/2d)$$

$$\sim m 2^{-(l+1)-kl} \prod_{d=1}^{l} \min(2^k, (n-m)/2d)$$

$$= m 2^{-(l+1)-kl} \prod_{d=1}^{l} (n-m)/2d^{l \log_2(n-m) - k}$$

$$\geq m 2^{-(l+1)-kl} (n-m)/2^{l(l+1)/2} \left( \frac{2^{k+1}}{n-m} \right)^{l \log_2(n-m) - k}$$

$$\geq m 2^{-(l+1)-l \log_2 n + l \log_2 n - l(l+1)/2 + l \log_2(n-m) - (l+1)/2 + l \log_2(n-m)} \times (\log n)^{2k-2 \log_2(n-m)}$$

$$= \exp \left( o(\log n) + \log m - l \log n - l^2 \log(2)/2 \\
+ l \log(n-m) + (2k - 2 \log_2(n-m)) \log \log n \right)$$

$$\geq \exp \left( o(\log n) + (a - 1) \log n - (3a - 4) \log(n)/2 \\
+ l \log(1 - m/n) - 2(2 \log_2 n + \log_2(1 - m/n)) \log \log n \right)$$

$$= \exp \left( o(\log n) + (1 - a/2) \log n \right).$$

Thus,

$$\sum_n e^{-M} = \sum_n e^{n^{1 - n/2 + o(1)}} < \infty. \quad \square$$

11
Propositions 4 and 5 together imply
\[ \frac{H_n - \log_2 n}{\sqrt{2 \log_2 n}} \to 1 \text{ almost surely.} \]
